Abstract

For a binary-input memoryless symmetric channel W , we consider the asymptotic behavior of the polarization process in the large block-length regime when transmission takes place over W . In particular, we study the asymptotics of the cumulative distribution $\mathbb{P}(Z_n \leq z)$, where $\{Z_n\}$ is the Bhattacharyya process defined from W , and its dependence on the rate of transmission. On the basis of this result, we characterize the asymptotic behavior, as well as its dependence on the rate, of the block error probability of polar codes using the successive cancellation decoder. This refines the original bounds by Arıkan and Telatar. Our results apply to general polar codes based on $\ell \times \ell$ kernel matrices.

We also provide lower bounds on the block error probability of polar codes using the MAP decoder. The MAP lower bound and the successive cancellation upper bound coincide when $\ell = 2$, but there is a gap for $\ell > 2$.

I. INTRODUCTION

A. Polar Codes

Polar codes, introduced by Arıkan [1], are a family of codes that provably achieve the capacity of binary-input memoryless symmetric (BMS) channels using low-complexity encoding and decoding algorithms. Since their invention, there has been a large body of work that has analyzed (see e.g., [2]–[11]) and extended (see e.g., [12]–[20]) these codes.

The construction of polar codes is based on an $\ell \times \ell$ matrix G , with entries in $\{0, 1\}$, called the kernel matrix. Besides being invertible, the matrix G should have the property that none of its column permutations is upper triangular [13]. We call a matrix G with such properties a *polarizing* matrix and in the following, whenever we speak of a kernel matrix G , we assume that G is polarizing.

The material in this paper was presented in part in [6], [7], [8] and [11].

The rows of the generator matrix of a polar code with block-length $N = \ell^n$ are chosen from the rows of the matrix

$$G^{\otimes n} \triangleq \overbrace{G \otimes G \otimes \cdots \otimes G}^n,$$

where $\otimes$ denotes the Kronecker product. For the case $\ell = 2$ and the choice $G = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix}$, Reed-Muller (RM) codes also fall into this category. However, the crucial difference between polar codes and RM codes lies in the choice of the rows. For RM codes, the rows of the largest weights are chosen, whereas for polar codes the choice is dependent on the channel and is made using a method called channel polarization. We briefly review this method and explain how polar codes are constructed from it. We also refer the reader to [1], [5] and [13] for a detailed discussion.

B. Channel Polarization

Let W be a BMS channel, and let $\mathcal{X} = \{0, 1\}$ denote its input alphabet, $\mathcal{Y}$ the output alphabet, and $W(y|x)$ the transition probabilities. Let $I(W) \in [0, 1]$ denote the mutual information between the input and output of W with uniform distribution on the input. The capacity of a BMS channel W is equal to $I(W)$. Also, the Bhattacharyya parameter of W , denoted by $Z(W)$, is defined as

$$Z(W) = \sum_{y \in \mathcal{Y}} \sqrt{W(y|0)W(y|1)}.$$

It provides upper and lower bounds of the error probability $P_e(W)$ in estimating the channel input x on the basis of the channel output y via the maximum-likelihood (ML) decoding of $W(y|x)$ as follows [22, Chapter 4], [5].

$$\frac{1}{2} \left(1 - \sqrt{1 - Z(W)^2} \right) \leq P_e(W) \leq \frac{1}{2} Z(W). \quad (1)$$

It is also related to the capacity $I(W)$ via

$$\begin{aligned} Z(W) + I(W) &\geq 1, \\ [Z(W)]^2 + [I(W)]^2 &\leq 1, \end{aligned}$$

both proved in [1].

The method of channel polarization is defined as follows. Take $N = \ell^n$ copies of a BMS channel W . Combine them by using the kernel matrix G to make a new set of ℓ^n channels $\{W_{\ell^n}^{(i)}\}_{1 \leq i \leq \ell^n}$. The construction of these channels is done by recursively applying a transform called channel splitting. Channel splitting is a transform which takes a BMS channel W as input and outputs ℓ BMS channels W^j , $0 \leq j \leq \ell - 1$. The channels W^j are constructed according to the following rule: Consider a random row vector $U_0^{\ell-1} = (U_0, \dots, U_{\ell-1})$ that is uniformly distributed over $\{0, 1\}^\ell$. Let $X_0^{\ell-1} = U_0^{\ell-1} G$, where the arithmetic is in $\text{GF}(2)$. Also, let $Y_0^{\ell-1}$ be the output of ℓ uses of W over the input $X_0^{\ell-1}$. We define the channel between $U_0^{\ell-1}$ and $Y_0^{\ell-1}$ by the transition probabilities

$$W_\ell(y_0^{\ell-1} | u_0^{\ell-1}) \triangleq \prod_{i=0}^{\ell-1} W(y_i | x_i) = \prod_{i=0}^{\ell-1} W(y_i | (u_0^{\ell-1} G)_i). \quad (2)$$

The channel $W^j : \{0, 1\} \rightarrow \mathcal{Y}^\ell \times \{0, 1\}^j$ is defined as the BMS channel with input u_j , output $(y_0^{\ell-1}, u_0^{j-1})$ and transition probabilities

$$W^j(y_0^{\ell-1}, u_0^{j-1} | u_j) = \frac{1}{2^{\ell-1}} \sum_{u_{j+1}^{\ell-1}} W_\ell(y_0^{\ell-1} | u_0^{\ell-1}). \quad (3)$$

Here and hereafter, u_i^j denotes the subvector $(u_i, \dots, u_j)$.

The construction of the channels $\{W_{\ell^n}^{(i)}\}_{1 \leq i \leq \ell^n}$ can be visualized in the following way [1]. Consider an infinite ℓ -ary tree with the root node placed at the top. To each vertex of the tree, we assign a channel in a way that the collection of all the channels that correspond to the vertices at depth n equals $\{W_{\ell^n}^{(i)}\}_{1 \leq i \leq \ell^n}$. We do this by a recursive procedure. Assign to the root node the channel W itself. From left to right, assign W^0 to $W^{\ell-1}$ to the children of the root node. In general, if Q is the channel that is assigned to vertex v , we assign Q^0 to $Q^{\ell-1}$, from left to right respectively, to the children of the node v . There are ℓ^n vertices at level n in this ℓ -ary tree. Assume that we label these vertices from left to right from 1 to ℓ^n . Let the channel assigned to the i th vertex, $1 \leq i \leq \ell^n$, be $W_{\ell^n}^{(i)}$. Also, let the ℓ -ary representation of $i - 1$ be $b_1 b_2 \dots b_n$, where b_1 is the most significant digit. Then we have

$$W_{\ell^n}^{(i)} = (((W^{b_1})^{b_2}) \dots)^{b_n}.$$

As an example, assuming $i = 7$, $n = 3$ and $\ell = 2$ we have $W_8^{(7)} = ((W^1)^1)^0$.

The channels $\{W_{\ell^n}^{(i)}\}_{1 \leq i \leq \ell^n}$ have the property that, as n grows large, a fraction close to $I(W)$ of the channels have capacity close to 1 (or Bhattacharyya parameter close to 0); and a fraction close to $1 - I(W)$ of the channels have capacity close to 0 (or Bhattacharyya parameter close to 1). The basic idea behind polar codes is to use those channels with capacity close to 1 for information transmission. Accordingly, given the rate $R < I(W)$ and block-length $N = \ell^n$, the rows of the generator matrix of a polar code of block-length N correspond to a subset of the rows of the matrix $G^{\otimes n}$ whose indices are chosen with the following rule: Choose a subset of size NR of the channels $\{W_{\ell^n}^{(i)}\}_{1 \leq i \leq \ell^n}$ with the least values for the Bhattacharyya parameter and choose the rows $G^{\otimes n}$ with the indices corresponding to those of the channels. For example, if the channel $W_{\ell^n}^{(i)}$ is chosen, then the j th row of $G^{\otimes n}$ is selected, where the ℓ -ary representation of $j - 1$ is the digit-reversed version of that of $i - 1$. We decode using a successive cancellation (SC) decoder. This algorithm decodes the bits one-by-one in a pre-chosen order that is closely related to how the row indices of $G^{\otimes n}$ are chosen.

C. Problem Formulation and Relevant Work

Let $\mathcal{I}$ be the set of indices of the NR channels in the set $\{W_{\ell^n}^{(i)}\}_{1 \leq i \leq \ell^n}$ with the least values for the Bhattacharyya parameter. Let $\mathbb{P}_e^{\text{SC}}(N, R)$ and $\mathbb{P}_e^{\text{MAP}}(N, R)$ denote the average block error probability of the SC and the maximum a-posteriori (MAP) decoders, respectively, with block-length N and rate R . For the SC decoder we have [1], [5],

$$\max_{i \in \mathcal{I}} \frac{1}{2} \left(1 - \sqrt{1 - Z(W_{\ell^n}^{(i)})^2} \right) \leq \mathbb{P}_e^{\text{SC}}(N, R) \leq \sum_{i \in \mathcal{I}} Z(W_{\ell^n}^{(i)}). \quad (4)$$

This relation evidently shows that the distribution of the Bhattacharyya parameters of the channels $\{W_{\ell^n}^{(i)}\}_{1 \leq i \leq \ell^n}$ plays a fundamental role in the analysis of polar codes. More precisely, for $n \in \mathbb{N} \triangleq \{0, 1, 2, \dots\}$ and

$0 < z < 1$, we are interested in analyzing the behavior of

$$F(n, z) = \frac{\#\{i : Z(W_{\ell^n}^{(i)}) \leq z\}}{\ell^n}, \quad (5)$$

where $\#A$ denotes the number of elements of the set A . There is an entirely equivalent probabilistic description of (5): Define the “polarization” process [2] of the channel W as a channel-valued stochastic process $\{W_n\}_{n \in \mathbb{N}}$ with $W_0 = W$ and

$$W_{n+1} = W_n^{B_n}, \quad (6)$$

where $\{B_n\}_{n \in \mathbb{N}}$ is a sequence of independent and identically-distributed (i.i.d.) random variables with distribution $\mathbb{P}(B_0 = j) = \frac{1}{\ell}$ for $j \in \{0, 1, \dots, \ell - 1\}$. In other words, the process begins at the root node of the infinite ℓ -ary tree introduced above, and in each step it chooses one of the ℓ children of the current node with uniform probability. So at time n , the process $\{W_n\}_{n \in \mathbb{N}}$ outputs one of the ℓ^n channels at level n of the tree uniformly at random. The Bhattacharyya process $\{Z_n\}_{n \in \mathbb{N}}$ of the channel W is defined from the polarization process as $Z_n \triangleq Z(W_n)$. In this setting we have

$$\mathbb{P}(Z_n \leq z) = F(n, z). \quad (7)$$

It was shown in [2] and [5] that the Bhattacharyya process $\{Z_n\}_{n \in \mathbb{N}}$ converges almost surely to a $\{0, 1\}$ -valued random variable Z_∞ with $\mathbb{P}(Z_\infty = 0) = I(W)$. Our objective is to investigate the asymptotic behavior of $\mathbb{P}(Z_n \leq z)$. The analysis of the process $\{Z_n\}_{n \in \mathbb{N}}$ around the point $z = 0$ is of particular interest, as this indicates how the “good” channels (i.e., the channels that have mutual information close to 1) behave. The asymptotic analysis of the process is closely related to the “partial distances” of the kernel matrix G :

Definition 1 (Partial Distances): We define the *partial distances* $D_i(G)$, $i = 0, \dots, \ell - 1$, of an $\ell \times \ell$ matrix $G = \begin{bmatrix} g_0 \\ \vdots \\ g_{\ell-1} \end{bmatrix}$ (g_i ’s are row vectors) as

$$\begin{aligned} D_i(G) &\triangleq d_H(\{g_i\}, \langle g_{i+1}, \dots, g_{\ell-1} \rangle), \quad i = 0, \dots, \ell - 2, \\ D_{\ell-1}(G) &\triangleq d_H(\{g_{\ell-1}\}, \{0\}), \end{aligned}$$

where $d_H(\cdot, \cdot)$ denotes the Hamming distance between two sets of binary sequences, and where $\langle g_{i+1}, \dots, g_{\ell-1} \rangle$ denotes the linear space spanned by $g_{i+1}, \dots, g_{\ell-1}$. The *exponent* of G is then defined as

$$E(G) = \frac{1}{\ell} \sum_{i=0}^{\ell-1} \log_\ell D_i(G),$$

and the *second exponent* of G is defined as

$$V(G) = \frac{1}{\ell} \sum_{i=0}^{\ell-1} (\log_\ell D_i(G) - E(G))^2.$$

In other words, the exponent $E(G)$ and the second exponent $V(G)$ are the mean and the variance of the random variable $\log_\ell D_B(G)$, where B is a random variable taking a value in $\{0, 1, \dots, \ell - 1\}$ with uniform probability. It should be noted that the invertibility of G implies the partial distances $\{D_i(G)\}$ to be strictly positive, making the exponent $E(G)$ finite. Note also that the condition for a matrix G to be polarizing, that none of column permutations of G is upper triangular, implies $\{D_i(G)\}$ to be strictly greater than 1, yielding $E(G)$ to be strictly positive.

The following theorem partially characterizes the behavior of the process $\{Z_n\}_{n \in \mathbb{N}}$ around $z = 0$.

Theorem 2 ([2] and [5]): Let W be a BMS channel and assume that we are using as the kernel matrix an $\ell \times \ell$ matrix G with exponent $E(G)$. For any fixed β with $0 < \beta < E(G)$,

$$\lim_{n \rightarrow \infty} \mathbb{P}(Z_n \leq 2^{-\ell^{n\beta}}) = I(W).$$

Conversely, if $I(W) < 1$, then for any fixed $\beta > E(G)$,

$$\lim_{n \rightarrow \infty} \mathbb{P}(Z_n \geq 2^{-\ell^{n\beta}}) = 1.$$

■

An important consequence of Theorem 2 is that, as the behavior of $\mathbb{P}_e^{\text{SC}}(N, R)$ when using polar codes with the kernel matrix G , of block-length $N = \ell^n$ and rate $R < I(W)$ under SC decoding is asymptotically the same as that of $\max_{i \in \mathcal{I}} Z(W_N^{(i)})$ from (4), the probability of error behaves as $2^{-\ell^{nE(G)+o(n)}}$ as N tends to infinity. A noteworthy point about this result is that the asymptotic analysis of the probability of error is rate-independent, provided that the rate R is less than the capacity $I(W)$. In this paper, we provide a refined estimate for $\mathbb{P}(Z_n \leq z)$. Specifically, we derive the asymptotic relation between $\mathbb{P}(Z_n \leq z)$ and the rate of transmission R . From this we derive the asymptotic behavior of $\mathbb{P}_e^{\text{SC}}(N, R)$ and its dependence on the rate of transmission. We further derive lower bounds on the error probability when we perform MAP decoding instead of SC decoding.

An important point to mention here is that the results of this paper are obtained in the asymptotic limit of the block-length for any *fixed* rate value R . Considering the regime where R also varies with the block-length is a problem of different interest, for which we refer the reader to [21].

The outline of the paper is as follows. In Section II we state the main results of the paper. In Section III we first define several auxiliary processes and provide bounds on their asymptotic behavior. Using these bounds, we then prove the main results. We discuss the implications of the proofs in selecting the set of channel indices in Section IV. It should be noted that in the following the logarithms are in base 2 unless explicitly stated otherwise.

II. MAIN RESULTS

Theorem 3: Consider an $\ell \times \ell$ polarizing kernel matrix $G = \begin{bmatrix} g_0 \\ \vdots \\ g_{\ell-1} \end{bmatrix}$. For a BMS channel W , let $\{Z_n = Z(W_n)\}_{n \in \mathbb{N}}$ be the Bhattacharyya process of W . Let $Q(t) \triangleq \int_t^\infty e^{-z^2/2} dz / \sqrt{2\pi}$ be the error function and $Q^{-1}(\cdot)$ be its inverse function.

1) For $R < I(W)$,

$$\lim_{n \rightarrow \infty} \mathbb{P}\left(Z_n \leq 2^{-\ell^{nE(G) + \sqrt{nV(G)}Q^{-1}\left(\frac{R}{I(W)}\right) + f(n)}}\right) = R.$$

2) Let $H = [g_{\ell-1}^T, \dots, g_0^T]^{-1}$ ($\cdot^T$ denotes the transpose) and assume that $D_i(H) \leq D_{i-1}(H)$ for $1 \leq i \leq \ell - 1$. Then, for $R' < 1 - I(W)$ we have,

$$\lim_{n \rightarrow \infty} \mathbb{P}\left(Z_n \geq 1 - 2^{-\ell^{nE(H) + \sqrt{nV(H)}Q^{-1}\left(\frac{R'}{1-I(W)}\right) + f(n)}}\right) = R'.$$

Here, $f(n)$ is any function satisfying $f(n) = o(\sqrt{n})$. ■

Discussion: Theorem 3 characterizes the asymptotic behavior of $\mathbb{P}(Z_n \leq z)$ and refines Theorem 2 in the following way. According to Theorem 2, if we transmit at rate R below the channel capacity, then the quantity

$\log_\ell(-\log(\mathbb{P}_e^{\text{SC}}(N = \ell^n, R)))$ scales like $nE(G) + o(n)$. The first part of Theorem 3 gives one further term by stating that $o(n)$ is in fact $\sqrt{nV(G)}Q^{-1}\left(\frac{R}{I(W)}\right) + o(\sqrt{n})$. The second part of Theorem 3, on the other hand, characterizes the asymptotic behavior of $\mathbb{P}(Z_n \leq z)$ near $z = 1$, which is important in applications of polar codes for source coding [12]. Put together, Theorem 3 characterizes the scaling of the error probability of polar codes with the SC decoder. Similar results hold for the case of the MAP decoder.

Theorem 4: Let W be a BMS channel and let $R < I(W)$ be the rate of transmission. Consider an $\ell \times \ell$ kernel matrix G with $\{w_0(G), \dots, w_{\ell-1}(G)\}$ the Hamming weights of its rows and define

$$E_w(G) = \frac{1}{\ell} \sum_{i=0}^{\ell-1} \log_\ell w_i(G), \quad V_w(G) = \frac{1}{\ell} \sum_{i=0}^{\ell-1} (\log_\ell w_i(G) - E_w(G))^2. \quad (8)$$

If we use polar codes of length $N = \ell^n$ and rate R for transmission, then the probability of error under MAP decoding, $\mathbb{P}_e^{\text{MAP}}(N, R)$, satisfies

$$\log_\ell(-\log(\mathbb{P}_e^{\text{MAP}}(N, R))) \leq nE_w(G) + \sqrt{nV_w(G)}Q^{-1}\left(\frac{R}{I(W)}\right) + o(\sqrt{n}). \quad (9)$$

■

Discussion: Let G be according to Arkan's original construction [1], i.e., $G = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix}$, which is the only polarizing matrix for the case $\ell = 2$. For this G , we have $w_i(G) = D_i(G)$ for $i = 0$ and 1 . Hence, the block error probability for the SC decoder and the MAP block error probability share the same asymptotic behavior according to Theorems 3 and 4. For a general $\ell \times \ell$ matrix G , however, one may have strict inequality $E_w(G) > E(G)$, in which case one still has an asymptotic gap between the error probability with SC decoding and the lower bound of MAP error probability. Whether or not this gap can be filled or made narrower is an open problem.

III. PROOF OF THE MAIN RESULT

A. Preliminaries

Let $\{B_n\}_{n \in \mathbb{N}}$ be a sequence of i.i.d. random variables that take their values in $\{0, 1, \dots, \ell-1\}$ with uniform probability, i.e., $\mathbb{P}(B_0 = j) = \frac{1}{\ell}$ for $j \in \{0, 1, \dots, \ell-1\}$. Let $(\Omega, \mathcal{F}, \mathbb{P})$ denote the probability space generated by the sequence $\{B_n\}_{n \in \mathbb{N}}$ and let $(\Omega_n, \mathcal{F}_n, \mathbb{P}_n)$ be the probability space generated by $(B_0, \dots, B_n)$. We now couple the polarization process $\{W_n\}_{n \in \mathbb{N}}$ with the sequence $\{B_n\}_{n \in \mathbb{N}}$ via (6). Consequently, the Bhattacharyya process $\{Z_n = Z(W_n)\}_{n \in \mathbb{N}}$ is coupled with the sequence $\{B_n\}_{n \in \mathbb{N}}$. By using the bounds given in [5, Chapter 5] we have the following relationship between the Bhattacharyya parameters of W^i and that of W : Recall that $\{D_i(G)\}_{0 \leq i \leq \ell-1}$ are the partial distances of the matrix G . We have [5]

$$Z(W)^{D_i(G)} \leq Z(W^i) \leq 2^{\ell-i} Z(W)^{D_i(G)}. \quad (10)$$

Also let $H = [g_{\ell-1}^T, \dots, g_0^T]^{-1}$. Assuming $D_i(H) \leq D_{i-1}(H)$,

$$(1 - Z(W))^{D_i(H)} \leq 1 - Z(W^i) \leq 2^{2i+1} (1 - Z(W))^{D_i(H)}. \quad (11)$$

B. Proof of Theorem 3

We first provide an intuitive picture behind the result of Theorem 3. For simplicity, assume $\ell = 2$ and let the channel W be a binary erasure channel (BEC) with erasure probability ϵ . The capacity of this channel is $1 - \epsilon$. For such a channel, the Bhattacharyya process has a simple closed form [1] as $Z_0 = \epsilon$ and

$$Z_{n+1} = \begin{cases} Z_n^2, & B_n = 0, \\ 2Z_n - Z_n^2, & B_n = 1. \end{cases} \quad (12)$$

We know from Section I-C that as n grows large, Z_n tends almost surely to a $\{0, 1\}$ -valued random variable Z_∞ with $\mathbb{P}(Z_\infty = 0) = 1 - \epsilon$. The asymptotic behavior of $\{Z_n\}$ can be explained roughly by considering the behavior of $\{-\log Z_n\}$. In particular, it is clear from (12) that at time $n + 1$, $-\log Z_n$ is either doubled (when $B_n = 0$), or decreased by at most 1 (when $B_n = 1$). Also, observe that once $-\log Z_n$ becomes sufficiently large, subtracting 1 from it has negligible effect compared with the doubling operation. Now assume that m is a sufficiently large number. Conditioned on the event that $-\log Z_m$ is a very large value (or equivalently, the value of Z_m is very close to 0: this happens with probability very close to $1 - \epsilon$), for $n > m$ the process $\{-\log Z_n\}$ evolves each time by being doubled if $B_n = 0$ or remaining roughly the same if $B_n = 1$. We can then use the central limit theorem to characterize the asymptotic behavior of $\{-\log Z_n\}$ for $n \gg m$.

The proof of Theorem 3 is done by making the above intuitive steps rigorous for a BMS channel W and a polarizing $\ell \times \ell$ kernel matrix G . In a slightly more general setting, we study the asymptotic properties of $\mathbb{P}(X_n \leq x)$ for any generic process $\{X_n\}_{n \in \mathbb{N}}$ satisfying the conditions (c1)–(c4) defined as follows.

Definition 5: Let S be a random variable taking values in $[1, \infty)$. Assume that the expectation and the variance of $\log S$ exist and are denoted by $\mathbb{E}[\log S]$ and $\mathbb{V}[\log S]$, respectively. Assume that $\{S_n\}_{n \in \mathbb{N}}$ are i.i.d. samples of S . Let $\{X_n \in (0, 1)\}_{n \in \mathbb{N}}$ be a random process satisfying the following conditions:

- (c1) There exists a random variable X_∞ such that $X_n \rightarrow X_\infty$ holds almost surely.
- (c2) $X_n^{S_n} \leq X_{n+1}$.
- (c3) There exists a constant $c \geq 1$ such that $X_{n+1} \leq cX_n^{S_n}$ holds.
- (c4) S_n is independent of X_m for $m \leq n$.

The random processes $\{Z_n\}_{n \in \mathbb{N}}$ and $\{1 - Z_n\}_{n \in \mathbb{N}}$ satisfy the above four conditions by letting $S_n = D_{B_n}(G)$ and $S_n = D_{B_n}(H)$, respectively. The fact that these processes satisfy the condition (c1) has been proved in [5, Lemma 5.4], and the result reads that if G is polarizing, then Z_∞ takes only 0 and 1, with probabilities $I(W)$ and $1 - I(W)$, respectively. Conditions (c2) and (c3) also hold because of (10) and (11).

Our objective now is to prove that for such a process $\{X_n\}_{n \in \mathbb{N}}$, we have

$$\lim_{n \rightarrow \infty} \mathbb{P} \left(X_n \leq 2^{-2^{n\mathbb{E}[\log S] + t\sqrt{n\mathbb{V}[\log S]} + f(n)}} \right) = \mathbb{P}(X_\infty = 0)Q(t), \quad (13)$$

where $f(n)$ is any function such that $f(n) = o(\sqrt{n})$ holds. The results of Theorem 3 then follow by noting that $\mathbb{P}(Z_\infty = 0) = I(W)$ and $\mathbb{P}(1 - Z_\infty = 0) = \mathbb{P}(Z_\infty = 1) = 1 - I(W)$ hold, and by substituting $t = Q^{-1}(R/I(W))$ and $t = Q^{-1}(R'/(1 - I(W)))$, respectively, into (13).

We prove (13) by showing the two inequalities obtained by replacing the equality in (13) by inequality in both directions. As the first step we have:

Lemma 6: Let $\{X_n\}_{n \in \mathbb{N}}$ be a random process satisfying (c1), (c3) and (c4). For any $f(n) = o(\sqrt{n})$,

$$\liminf_{n \rightarrow \infty} \mathbb{P} \left(X_n \leq 2^{-2^{n\mathbb{E}[\log S] + t\sqrt{n\mathbb{V}[\log S]} + f(n)}} \right) \geq \mathbb{P}(X_\infty = 0)Q(t).$$

Proof: Without loss of generality, we can assume that c in condition (c3) satisfies $c \geq 2$. Define the process $\{L_n\}_{n \in \mathbb{N}}$ as $L_n \triangleq \log X_n$. From (c3), we have

$$L_n \leq \log c + S_{n-1}L_{n-1},$$

and by applying the above relation recursively, for $m \leq n-1$ we obtain

$$\begin{aligned} L_n &\leq \left(\sum_{j=m}^{n-1} \prod_{i=j+1}^{n-1} S_i \right) \log c + \left(\prod_{i=m}^{n-1} S_i \right) L_m \\ &\leq \left(\prod_{i=m}^{n-1} S_i \right) ((n-m) \log c + L_m). \end{aligned} \quad (14)$$

Fix $\beta \in (0, \mathbb{E}[\log S])$ and let

$$m \triangleq (\log n + \log \log c) / \beta. \quad (15)$$

Conditioned on the event $\mathcal{D}_m(\beta) \triangleq \{X_m < 2^{-2^{\beta m}}\}$, by using (14) we obtain

$$L_n \leq - \left(\prod_{i=m}^{n-1} S_i \right) m \log c.$$

Let the event $\mathcal{H}_m^{n-1}(t)$ be defined as

$$\mathcal{H}_m^{n-1}(t) \triangleq \left\{ \sum_{i=m}^{n-1} \log S_i \geq (n-m)\mathbb{E}[\log S] + t\sqrt{(n-m)\mathbb{V}[\log S]} + f(n-m) \right\},$$

where f is any function such that $f(k) = o(\sqrt{k})$ holds. Conditioned on $\mathcal{D}_m(\beta)$ and $\mathcal{H}_m^{n-1}(t)$, we have

$$\log(-L_n) \geq \log m + \log \log c + (n-m)\mathbb{E}[\log S] + t\sqrt{(n-m)\mathbb{V}[\log S]} + f(n-m).$$

Hence,

$$\begin{aligned} \mathbb{P} \left(\log(-L_n) \geq \log m + \log \log c + (n-m)\mathbb{E}[\log S] + t\sqrt{(n-m)\mathbb{V}[\log S]} + f(n-m) \right) \\ \geq \mathbb{P}(\mathcal{D}_m(\beta) \cap \mathcal{H}_m^{n-1}(t)) = \mathbb{P}(\mathcal{D}_m(\beta))\mathbb{P}(\mathcal{H}_m^{n-1}(t)). \end{aligned}$$

The last equality follows from the independence condition (c4).

Note that taking the limit $n \rightarrow \infty$ also implies $m \rightarrow \infty$ and $n-m \rightarrow \infty$ via (15). From Theorem 10 (in Appendix), we have $\lim_{n \rightarrow \infty} \mathbb{P}(\mathcal{D}_m(\beta)) = \mathbb{P}(X_\infty = 0)$. We also have $\lim_{n \rightarrow \infty} \mathbb{P}(\mathcal{H}_m^{n-1}(t)) = Q(t)$ due to the central limit theorem for $\{\log S_i\}$. We consequently have

$$\liminf_{n \rightarrow \infty} \mathbb{P} \left(\log(-\log X_n) \geq n\mathbb{E}[\log S] + t\sqrt{n\mathbb{V}[\log S]} + f(n) \right) \geq \mathbb{P}(X_\infty = 0)Q(t)$$

for any $f(n) = o(\sqrt{n})$. ■

The second step of the proof of (13) is to prove the other direction of the inequality. We have:

Lemma 7: Let $\{X_n\}_{n \in \mathbb{N}}$ be a random process satisfying (c1), (c2) and (c4). For any $f(n) = o(\sqrt{n})$,

$$\limsup_{n \rightarrow \infty} \mathbb{P} \left(X_n \leq 2^{-2^{n\mathbb{E}[\log S] + t\sqrt{n\mathbb{V}[\log S]} + f(n)}} \right) \leq \mathbb{P}(X_\infty = 0)Q(t).$$

Proof: Let $L_n \triangleq \log X_n$. From (c2), for $m \leq n-1$ we have

$$\begin{aligned} L_n &\geq S_{n-1} L_{n-1} \\ &\geq \left(\prod_{i=m}^{n-1} S_i \right) L_m, \end{aligned}$$

and thus

$$\log(-L_n) \leq \sum_{i=m}^{n-1} \log S_i + \log(-L_m). \quad (16)$$

Hence, for any fixed m and any $\delta \in (0, 1)$,

$$\begin{aligned} &\limsup_{n \rightarrow \infty} \mathbb{P} \left(\log(-L_n) > n\mathbb{E}[\log S] + t\sqrt{n\mathbb{V}[\log S]} + f(n) \right) \\ &\leq \limsup_{n \rightarrow \infty} \mathbb{P} \left(\log(-L_n) > n\mathbb{E}[\log S] + t\sqrt{n\mathbb{V}[\log S]} + f(n), X_m \leq \delta \right) \\ &\quad + \limsup_{n \rightarrow \infty} \mathbb{P} \left(\log(-L_n) > n\mathbb{E}[\log S] + t\sqrt{n\mathbb{V}[\log S]} + f(n), X_m > \delta \right). \end{aligned} \quad (17)$$

The first term in the right-hand side of (17) is upper bounded as

$$\begin{aligned} &\limsup_{n \rightarrow \infty} \mathbb{P} \left(\log(-L_n) > n\mathbb{E}[\log S] + t\sqrt{n\mathbb{V}[\log S]} + f(n), X_m \leq \delta \right) \\ &\stackrel{(a)}{\leq} \limsup_{n \rightarrow \infty} \mathbb{P} \left(\sum_{i=m}^{n-1} \log S_i + \log(-L_m) > n\mathbb{E}[\log S] + t\sqrt{n\mathbb{V}[\log S]} + f(n), X_m \leq \delta \right) \\ &\stackrel{(b)}{=} Q(t)\mathbb{P}(X_m \leq \delta), \end{aligned}$$

where (a) follows from (16), and where (b) follows from (c4) and the central limit theorem. The second term in the right-hand side of (17) is upper bounded as

$$\begin{aligned} &\limsup_{n \rightarrow \infty} \mathbb{P} \left(\log(-L_n) > n\mathbb{E}[\log S] + t\sqrt{n\mathbb{V}[\log S]} + f(n), X_m > \delta \right) \\ &\leq \limsup_{n \rightarrow \infty} \mathbb{P} \left(X_n \leq \frac{\delta}{2}, X_m > \delta \right) \\ &\stackrel{(a)}{\leq} \mathbb{P} \left(X_\infty \leq \frac{\delta}{2}, X_m > \delta \right), \end{aligned}$$

where (a) follows from (c1). Applying these bounds to (17), for any $\delta \in (0, 1)$, we have

$$\begin{aligned} &\limsup_{n \rightarrow \infty} \mathbb{P} \left(\log(-L_n) > n\mathbb{E}[\log S] + t\sqrt{n\mathbb{V}[\log S]} + f(n) \right) \\ &\leq \limsup_{m \rightarrow \infty} \left\{ Q(t)\mathbb{P}(X_m \leq \delta) + \mathbb{P} \left(X_\infty \leq \frac{\delta}{2}, X_m > \delta \right) \right\} \\ &\leq Q(t)\mathbb{P}(X_\infty \leq \delta) + \mathbb{P} \left(X_\infty \leq \frac{\delta}{2}, X_\infty \geq \delta \right) \\ &= Q(t)\mathbb{P}(X_\infty \leq \delta). \end{aligned}$$

By letting $\delta \rightarrow 0$, we obtain the result. ■

C. Proof of Theorem 4

Lemma 8: The MAP error probability of a linear code $\mathcal{C}$ over a BMS channel W is lower bounded by $Z(W)^{2d_{\min}}/4$ where $d_{\min}$ is the minimum distance of $\mathcal{C}$.

Proof: Within this proof, the notation $\mathbb{P}(\cdots)$ should be understood as generically denoting the probability of an event $(\cdots)$. Since the MAP error probability of a linear code over a BMS channel does not depend on transmitted codeword, we can assume without loss of generality that transmitted codeword is the all-zero codeword, which is denoted by $\mathbf{0}$. Let $\mathbf{Y}$ be the random variable corresponding to a received sequence when $\mathbf{0}$ is transmitted and let $P(y|c)$ be the likelihood of a codeword c given a received sequence y . Since MAP and ML are equivalent for equiprobable codewords, the MAP error probability is lower bounded as

$$\begin{aligned} \mathbb{P}(\cup_{c' \in \mathcal{C} \setminus \{\mathbf{0}\}} \{P(\mathbf{Y} | c') \geq P(\mathbf{Y} | \mathbf{0})\}) &\geq \mathbb{P}(P(\mathbf{Y} | c) \geq P(\mathbf{Y} | \mathbf{0})) \\ &= P_e(W^{\otimes w(c)}) \\ &\stackrel{(a)}{\geq} \frac{1}{2} \left(1 - \sqrt{1 - Z(W^{\otimes w(c)})^2}\right) \\ &= \frac{1}{2} \left(1 - \sqrt{1 - Z(W)^{2w(c)}}\right) \\ &\geq \frac{1}{4} Z(W)^{2w(c)}. \end{aligned}$$

Here, c is an arbitrary codeword in the set $\mathcal{C} \setminus \{\mathbf{0}\}$ and $w(c)$ denotes its Hamming weight. Also $W^{\otimes m}$ denotes the m -parallel channel of W which has the following rule

$$W^{\otimes m}(y_1^m | x) \triangleq \prod_{i=1}^m W(y_i | x). \quad (18)$$

Step (a) follows from (1). ■

It should be noted that the lower bound $P_e(W^{\otimes w(c)}) \geq (1/4)Z(W)^{2w(c)}$ in the proof of Lemma 8 is not asymptotically tight in terms of the conventional exponents. It is possible to obtain tighter lower bounds via more elaborate arguments as in [22, Chapter 4]. However, since we are only interested in behavior of double exponents, the above bound turns out to be sufficient for the purpose of proving Theorem 4.

In order to prove Theorem 4, from Lemma 8 it is sufficient to prove that given any $\epsilon > 0$ there exists an integer $M \in \mathbb{N}$ such that for $n \geq M$,

$$\log_\ell(d(n, R)) \leq nE_w(G) + \sqrt{nV_w(G)} \left(Q^{-1} \left(\frac{R}{I(W)} \right) + \epsilon \right),$$

where $d(n, R)$ is the minimum distance of a polar code using the kernel matrix G , with block-length $N = \ell^n$ and rate R . Since a row weight of the generator matrix is an upper bound of the minimum distance for a linear code, and since the weight of the i th row of $G^{\otimes n}$ is equal to $\prod_{j=1}^n w_{i_j}(G)$, where i_j is the j th digit of the ℓ -ary representation of $i - 1$, it is therefore sufficient to prove that given any $\epsilon > 0$, there exists an integer $M \in \mathbb{N}$ such that for a polar code of block-length $N = \ell^n \geq \ell^M$ and rate R and set of chosen indices $\mathcal{I}$, there exists $i \in \mathcal{I}$ for which the inequality

$$\sum_{j=1}^n \log_\ell w_{i_j}(G) \leq nE_w(G) + \sqrt{nV_w(G)} \left(Q^{-1} \left(\frac{R}{I(W)} \right) + \epsilon \right) \quad (19)$$

holds. In the proof of Theorem 3, one can observe that the key idea is to apply central limit theorem for $\{\log S_n = \log D_{B_n}(G)\}_{n \in \mathbb{N}}$. In the same sense, in order to prove Theorem 4 we consider the random process $\{\log w_{B_n}(G)\}_{n \in \mathbb{N}}$ in addition to $\{\log D_{B_n}(G)\}_{n \in \mathbb{N}}$. Note that these processes are in general correlated since they are both coupled to the same process $\{B_n\}_{n \in \mathbb{N}}$. These processes are equal with probability one in the special case where $D_i(G) = w_i(G)$ holds for all $i \in \{0, 1, \dots, \ell - 1\}$. In the same manner as the proof

of Theorem 3, we move on to a more abstract setting, by introducing a random variable U taking values in $[1, \infty)$, for which we assume that the expectation and the variance of $\log U$ exist and are denoted by $\mathbb{E}[\log U]$ and $\mathbb{V}[\log U]$, respectively, and by letting $\{(S_n, U_n)\}_{n \in \mathbb{N}}$ be i.i.d. drawings of (S, U) , where S is defined as in Definition 5. Let $\{(X_n, S_n, U_n)\}_{n \in \mathbb{N}}$ be a random process such that $\{(X_n, S_n)\}_{n \in \mathbb{N}}$ satisfies the conditions (c1) to (c4) together with the additional condition (c5) for $\{U_n\}_{n \in \mathbb{N}}$.

(c5) U_n is independent of X_m for $m \leq n$.

It is easy to see that the stochastic process of the triplets $\{(Z_n, D_{B_n}(G), w_{B_n}(G))\}_{n \in \mathbb{N}}$ satisfies (c1) to (c5). We first note from the proof of Theorem 3 that for any generic process $\{(X_n, S_n, U_n)\}_{n \in \mathbb{N}}$ satisfying (c1) to (c5), the relation (13) holds for any function $f(n) = o(\sqrt{n})$. We also claim that for real numbers v, t such that $v > t$ and for any function $g(n) = o(\sqrt{n})$ we have

$$\limsup_{n \rightarrow \infty} \mathbb{P} \left(X_n \leq 2^{-2^{n\mathbb{E}[\log S] + t\sqrt{n\mathbb{V}[\log S]} + f(n)}}, \right. \\ \left. \sum_{i=0}^{n-1} \log U_i > n\mathbb{E}[\log U] + v\sqrt{n\mathbb{V}[\log U]} + g(n) \right) < \mathbb{P}(X_\infty = 0)Q(t). \quad (20)$$

Using the relations (13) and (20) it is easy to see that for generator matrices of polar codes with rate R , the number of rows satisfying (19) is asymptotically proportional to the block-length, and hence there exists at least a row satisfying (19). We now turn to the proof of (20).

Lemma 9: Let $\{(X_n, S_n, U_n)\}_{n \in \mathbb{N}}$ be a random process satisfying (c1) to (c5). For any $f(n) = o(\sqrt{n})$ and $g(n) = o(\sqrt{n})$,

$$\lim_{n \rightarrow \infty} \mathbb{P} \left(X_n \leq 2^{-2^{n\mathbb{E}[\log S] + t\sqrt{n\mathbb{V}[\log S]} + f(n)}}, \sum_{i=0}^{n-1} \log U_i > n\mathbb{E}[\log U] + v\sqrt{n\mathbb{V}[\log U]} + g(n) \right) \\ = \mathbb{P}(X_\infty = 0)\mathbb{P}(A_S \geq t, A_U \geq v),$$

where (A_S, A_U) are Gaussian random variables of mean zero whose covariance matrix is equal to that of

$$\left(\frac{\log S - \mathbb{E}[\log S]}{\sqrt{\mathbb{V}[\log S]}}, \frac{\log U - \mathbb{E}[\log U]}{\sqrt{\mathbb{V}[\log U]}} \right).$$

The proof of this Lemma is the same as the proofs of Lemma 6 and Lemma 7. The difference is that the central limit theorem is replaced by the two-dimensional central limit theorem. From $\mathbb{P}(A_S \geq t, A_U \geq v) \leq Q(\max\{t, v\})$, the relation (20) is obtained for $v > t$. This completes the proof of Theorem 4.

Remark: Let $G = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix}$. For this choice of G , we have $w_i(G) = D_i(G)$ for $i = 0$ and 1. Hence, the random variables $S_n = D_{B_n}(G)$ and $U_n = w_{B_n}(G)$ are equal for $n \in \mathbb{N}$. Also note that S_n takes its value in the set $\{1, 2\}$ uniformly at random. From the proof of Theorem 4, the set of indices of the rows of polar codes with the kernel matrix G and rate R correspond to the event

$$\left\{ X_n \leq 2^{-2^{n\mathbb{E}[\log S] + Q^{-1}\left(\frac{R}{I(W)}\right)\sqrt{n\mathbb{V}[\log S]} + f(n)}} \right\}.$$

Also, with the same G , the set of indices of a RM code with rate R' correspond to the event

$$\left\{ \sum_{i=0}^{n-1} \log U_i > n\mathbb{E}[\log U] + Q^{-1}(R')\sqrt{n\mathbb{V}[\log U]} + g(n) \right\}.$$

From Lemma 9, it is easy to conclude that the fraction of the common chosen row indices of $G^{\otimes n}$ between polar codes of rate R and RM codes of rate R' tends to $I(W) \min\{\frac{R}{I(W)}, R'\}$ as $n \rightarrow \infty$.

IV. SELECTION RULE OF ROWS

The proof of Lemma 6 suggests a way to help us select the good indices in a more computationally efficient way. In the proof, ℓ -ary expansion of row indices of $G^{\otimes n}$ corresponds to realizations of $B_1, \dots, B_n$. The proof of Lemma 6 implies that it is sufficient to select rows in $\mathcal{D}_m(\beta) \cap \mathcal{H}_m^{n-1}(t)$ in order to achieve the asymptotically optimum performance. It should be noted that the event $\mathcal{D}_m(\beta)$ applied to the Bhattacharyya process $\{Z_n = Z(W_n)\}_{n \in \mathbb{N}}$ of W depends on the channel W , whereas the event $\mathcal{H}_m^{n-1}(t)$ is channel-independent. This observation leads to the following selection rule: The first $m = s(n) \triangleq (\log n + \log \log c)/\beta$ digits of the row indices are determined in the channel-dependent way. Then, the following $(n - m)$ digits are determined in the RM way, i.e., those combinations of digits $(B_m, \dots, B_{n-1})$ giving large values of $\sum_{i=m}^{n-1} \log D_{B_i}(G)$ are selected. In this rule, only the first $\Theta(\log n)$ digits should be determined depending on the channel.

The above argument can further be extended in a recursive manner. Let $\mathcal{C}_m^{n-1}(\epsilon) \triangleq \{(n-m)^{-1} \sum_{i=m}^{n-1} \log S_i \geq \mathbb{E}[\log S] - \epsilon\}$. Then, it is sufficient to select rows in $\mathcal{D}_{m_0}(\beta) \cap \mathcal{C}_{m_0}^{m_1-1}(\epsilon) \cap \mathcal{H}_{m_1}^{n-1}(t)$ where $m_1 = s(n)$ and $m_0 = s(m_1)$ since $\mathcal{D}_{m_1}(\beta)$ and $\mathcal{D}_{m_0}(\beta) \cap \mathcal{C}_{m_0}^{m_1-1}(\mathbb{E}[\log S] - \beta)$ are asymptotically equal. (Use $\mathcal{C}_m^{n-1}(\epsilon)$ instead of $\mathcal{H}_m^{n-1}(t)$ in the proof of Lemma 6. A similar argument can be found in [1, Section IV-B].) From this observation, only $\Theta(\log \log n)$ digits have to be determined depending on the channel. By iterating this argument, we obtain the selection rule in which only

$$\Theta(\overbrace{\log \cdots \log n}^k) \quad (21)$$

digits depend on the channel for any $k \in \mathbb{N}$. From the argument so far, we deduce that even though the behavior of $Z_n = Z(W_n)$ depends on the channel W as well as the whole sequence $\{B_0, B_1, \dots, B_{n-1}\}$, the “fate” regarding whether it approaches 0 or 1 when n is large, is mostly determined by the channel W and a prefix of $\{B_0, B_1, \dots, B_{n-1}\}$ with a relatively small length. Thus, to choose the indices of the channels $W_{\ell^n}^{(i)}$ that have the best quality, the first sublinear number of significant bits of the ℓ -ary expansion of $i-1$ are determined depending on the channel and the rest are determined in a RM-like fashion. It should be noted that the above argument is valid in the large- n asymptotics. It does not mean that one can make the number of digits to be determined in the channel-dependent manner arbitrarily small.

Although the good indices of the rows of $G^{\otimes n}$ can be selected using density evolution [3], in practice storage and convolution of probability density functions is exponentially (in block-length N) costly in terms of memory and computation. Recently, several authors have considered accurate and efficient implementation of the density evolution procedure [23], [24]. The above-mentioned construction rule can be useful in reducing the number of convolutions and the number of levels in the quantization of channels.

APPENDIX

Theorem 10: Let $\{X_n \in (0, 1)\}_{n \in \mathbb{N}}$ be a random process satisfying (c1) and (c3). For any fixed $\beta \in (0, \mathbb{E}[\log S])$,

$$\lim_{n \rightarrow \infty} \mathbb{P}(X_n \leq 2^{-2^{\beta n}}) = \mathbb{P}(X_\infty = 0).$$

Remark: Although Theorem 10 has already been stated for Bhattacharyya processes $\{Z_n\}_{n \in \mathbb{N}}$ in [2], [5], we would nevertheless like to confirm that the result is obtained by using only the two conditions (c1) and (c3).

Proof of Theorem 10: As the inequality

$$\limsup_{n \rightarrow \infty} \mathbb{P}(X_n \leq 2^{-2^{\beta n}}) \leq \mathbb{P}(X_\infty = 0)$$

obviously holds, a proof of the lower bound

$$\liminf_{n \rightarrow \infty} \mathbb{P} \left(X_n \leq 2^{-2^{\beta n}} \right) \geq \mathbb{P}(X_\infty = 0)$$

is given in the following. Fix $\epsilon \in (0, 1)$. Let $\{J_n\}_{n \in \mathbb{N}}$ be the random process defined as

$$J_n \triangleq \begin{cases} \log(-\log X_n), & \text{for } n = 0, \dots, m \\ \log(S_{n-1} - \epsilon) + J_{n-1}, & \text{for } n > m, \end{cases}$$

which is to be used for deriving a probabilistic bound for $\{X_n\}_{n \in \mathbb{N}}$. Let $\mathcal{T}_m^n(\gamma) \triangleq \{X_i < \gamma, \text{ for } i = m, m+1, \dots, n\}$. Fix $k \in \{1, 2, \dots\}$. From (c3), conditioned on $\mathcal{T}_m^{m+k-1}(c^{-1/\epsilon})$, the inequality $\log(-\log X_n) \geq J_n$ holds for $n = m, m+1, \dots, m+k$. For the process $\{J_n\}_{n \in \mathbb{N}}$, the inequality

$$\begin{aligned} J_{m+k} &= J_m + \sum_{i=m}^{m+k-1} \log(S_i - \epsilon) \\ &\geq J_m + \sum_{i=m}^{m+k-1} (\log S_i + \log(1 - \epsilon)) \end{aligned}$$

holds since $S_i \geq 1$. This inequality immediately implies the following conditional bound: Conditioned on $\mathcal{C}_m^{m+k-1}(\epsilon) \triangleq \{(1/k) \sum_{i=m}^{m+k-1} \log S_i \geq \mathbb{E}[\log S] - \epsilon\}$, one has

$$J_{m+k} \geq J_m + k(\mathbb{E}[\log S] - \epsilon + \log(1 - \epsilon)).$$

We have therefore obtained a probabilistic bound of $\log(-\log X_{m+k})$ of the form

$$\begin{aligned} \mathbb{P}(\log(-\log X_{m+k}) \geq J_m + k(\mathbb{E}[\log S] - \epsilon + \log(1 - \epsilon))) \\ \geq \mathbb{P} \left(\mathcal{T}_m^{m+k-1}(c^{-1/\epsilon}) \cap \mathcal{C}_m^{m+k-1}(\epsilon) \right) \\ \geq \mathbb{P} \left(\mathcal{T}_m^{m+k-1}(c^{-1/\epsilon}) \right) + \mathbb{P} \left(\mathcal{C}_m^{m+k-1}(\epsilon) \right) - 1, \end{aligned}$$

for any $m \in \mathbb{N}$, $k \in \mathbb{N}$ and $\epsilon > 0$. From the law of large numbers, $\lim_{k \rightarrow \infty} \mathbb{P}(\mathcal{C}_m^{m+k-1}(\epsilon)) = 1$. From (c1), $\lim_{m \rightarrow \infty} \lim_{k \rightarrow \infty} \mathbb{P}(\mathcal{T}_m^{m+k-1}(c^{-1/\epsilon})) \geq \mathbb{P}(X_\infty < c^{-1/\epsilon})$. Hence,

$$\begin{aligned} \liminf_{m \rightarrow \infty} \liminf_{k \rightarrow \infty} \\ \mathbb{P}(\log(-\log X_{m+k}) \geq J_m + k(\mathbb{E}[\log S] - \epsilon + \log(1 - \epsilon))) \\ \geq \mathbb{P}(X_\infty < c^{-1/\epsilon}) \geq \mathbb{P}(X_\infty = 0) \end{aligned}$$

holds for any $\epsilon > 0$. On the other hand, we observe that

$$\begin{aligned} \liminf_{n \rightarrow \infty} \mathbb{P} \left(\frac{1}{n} \log(-\log X_n) \geq \mathbb{E}[\log S] - \gamma \right) \\ \geq \liminf_{k \rightarrow \infty} \\ \mathbb{P}(\log(-\log X_{m+k}) \geq J_m + k(\mathbb{E}[\log S] - \epsilon + \log(1 - \epsilon))) \end{aligned}$$

holds for any fixed $m \in \mathbb{N}$ and $\gamma > \phi(\epsilon) \triangleq \epsilon - \log(1 - \epsilon)$. Hence,

$$\begin{aligned} \liminf_{n \rightarrow \infty} \mathbb{P} \left(\frac{1}{n} \log(-\log X_n) \geq \mathbb{E}[\log S] - \gamma \right) \\ \geq \mathbb{P}(X_\infty = 0) \end{aligned}$$

for any $\gamma > 0$ since $\phi(\epsilon) > 0$ for $\epsilon > 0$ and $\lim_{\epsilon \rightarrow 0} \phi(\epsilon) = 0$. ■
